enum in Java

Difficulty Level: Medium Last Updated: 24 Jan, 2022

Enumerations serve the purpose of representing a group of named constants in a programming language. For example, the 4 suits in a deck of playing cards may be 4 enumerators named Club, Diamond, Heart, and Spade, belonging to an enumerated type named Suit. Other examples include natural enumerated types (like the planets, days of the week, colors, directions, etc.).

Enums are used when we know all possible values at compile-time, such as choices on a menu, rounding modes, command-line flags, etc. It is not necessary that the set of constants in an enum type stay **fixed** for all time.

In Java (from 1.5), enums are represented using **enum** data type. Java enums are more powerful than <u>C/C++ enums</u>. In Java, we can also add variables, methods, and constructors to it. The main objective of enum is to define our own data types(Enumerated Data Types).

Declaration of enum in Java: Enum declaration can be done outside a Class or inside a Class but not inside a Method.

```
// A simple enum example where enum is declared
// outside any class (Note enum keyword instead of
// class keyword)
enum Color {
    RED,
    GREEN,
    BLUE;
}
public class Test {
    // Driver method
    public static void main(String[] args)
    {
        Color c1 = Color.RED;
        System.out.println(c1);
    }
}
```

RED

```
// enum declaration inside a class.

public class Test {
    enum Color {
        RED,
        GREEN,
        BLUE;
    }

    // Driver method
    public static void main(String[] args)
    {
        Color c1 = Color.RED;
        System.out.println(c1);
    }
}
```

Output

RED

- The first line inside the enum should be a list of constants and then other things like methods, variables, and constructors.
- According to <u>Java naming conventions</u>, it is recommended that we name constant with all capital letters

Important Points of enum:

Every enum is internally implemented by using Class.

```
/st internally above enum Color is converted to class Color
```

```
public static final Color RED = new Color();
public static final Color BLUE = new Color();
public static final Color GREEN = new Color();
}*/
```

- Every enum constant represents an **object** of type enum.
- enum type can be passed as an argument to **switch** statements.

```
// A Java program to demonstrate working on enum
// in switch case (Filename Test. Java)
import java.util.Scanner;
// An Enum class
enum Day {
   SUNDAY,
   MONDAY,
    TUESDAY,
   WEDNESDAY,
    THURSDAY,
    FRIDAY,
   SATURDAY;
}
// Driver class that contains an object of "day" and
// main().
public class Test {
    Day day;
    // Constructor
    public Test(Day day) { this.day = day; }
    // Prints a line about Day using switch
    public void dayIsLike()
    {
        switch (day) {
        case MONDAY:
            System.out.println("Mondays are bad.");
            break;
        case FRIDAY:
            System.out.println("Fridays are better.");
            break:
        case SATURDAY:
        case SUNDAY:
            System.out.println("Weekends are best.");
```

```
break;
default:
    System.out.println("Midweek days are so-so.");
    break;
}

// Driver method
public static void main(String[] args)
{
    String str = "MONDAY";
    Test t1 = new Test(Day.valueOf(str));
    t1.dayIsLike();
}
```

Mondays are bad.

- Every enum constant is always implicitly **public static final**. Since it is **static**, we can access it by using the enum Name. Since it is **final**, we can't create child enums.
- We can declare the main() method inside the enum. Hence we can invoke enum directly from the Command Prompt.

```
// A Java program to demonstrate that we can have
// main() inside enum class.

enum Color {
    RED,
    GREEN,
    BLUE;

    // Driver method
    public static void main(String[] args)
    {
        Color c1 = Color.RED;
        System.out.println(c1);
    }
}
```

RED

Enum and Inheritance:

- All enums implicitly extend java.lang.Enum class. As a class can only
 extend one parent in Java, so an enum cannot extend anything else.
- toString() method is overridden in java.lang.Enum class, which returns enum constant name.
- · enum can implement many interfaces.

values(), ordinal() and valueOf() methods:

- These methods are present inside java.lang.Enum.
- values() method can be used to return all values present inside the enum.
- Order is important in enums. By using the ordinal() method, each enum constant index can be found, just like an array index.
- valueOf() method returns the enum constant of the specified string value if exists.

```
// Java program to demonstrate working of values(),
// ordinal() and valueOf()
enum Color {
   RED,
    GREEN,
    BLUE;
}
public class Test {
    public static void main(String[] args)
        // Calling values()
        Color arr[] = Color.values();
        // enum with loop
        for (Color col : arr) {
            // Calling ordinal() to find index
            // of color.
            System.out.println(col + " at index "
                               + col.ordinal());
        }
```

```
// Using valueOf(). Returns an object of
// Color with given constant.
// Uncommenting second line causes exception
// IllegalArgumentException
System.out.println(Color.valueOf("RED"));
// System.out.println(Color.valueOf("WHITE"));
}
```

```
RED at index 0

GREEN at index 1

BLUE at index 2

RED
```

enum and constructor:

- enum can contain a constructor and it is executed separately for each enum constant at the time of enum class loading.
- We can't create enum objects explicitly and hence we can't invoke enum constructor directly.

enum and methods:

enum can contain both concrete methods and abstract methods. If an enum class
has an abstract method, then each instance of the enum class must implement it

```
// Java program to demonstrate that enums can have
// constructor and concrete methods.

// An enum (Note enum keyword inplace of class keyword)
enum Color {
    RED,
    GREEN,
    BLUE;

    // enum constructor called separately for each
    // constant
```

```
private Color()
    {
        System.out.println("Constructor called for : "
                           + this.toString());
    }
    public void colorInfo()
        System.out.println("Universal Color");
    }
}
public class Test {
    // Driver method
    public static void main(String[] args)
        Color c1 = Color.RED;
        System.out.println(c1);
        c1.colorInfo();
    }
}
```

```
Constructor called for : RED
Constructor called for : GREEN
Constructor called for : BLUE
RED
Universal Color
```
